fertilizer are applied to 100 different 1-devel 2 is 50% of the manufacturer's re researcher plans to apply treatment levels.	new fertilizer on crop yields plans to carry out an experiment in which different amounts of the acre parcels of land. There will be four treatment levels. Treatment level 1 is no fertilizer, treatment commended amount of fertilizer, treatment level 3 is 100%, and treatment level 4 is 150%. The wel 1 to the first 25 parcels of land, treatment level 2 to the second 25 parcels, and so forth.
Can you suggest a better way to assig	n treatment levels?
O A. Assign 150% of the manufactu	rer's recommended amount of fertilizer level to each parcel.
OB. Assign 50% of the manufacture	er's recommended amount of fertilizer level to each parcel.
Oc. Assign 100% of the manufactu	rer's recommended amount of fertilizer level to each parcel.
O. Assign the fertilizer treatment le	evel randomly to each parcel.
Why is your proposal better than the re	esearcher's method?
○ A. The researcher's method may	be flawed because it does not assign equal amounts of fertilizer to all parcels.
O B. The researcher's method may	be flawed because the different groups of parcels might differ systematically.
O. The researcher's method may	be flawed because it involves too few treatment levels.
On. The researcher's method is independent	eed the optimal design.
Answers D. Assign the fertilizer treatr	nent level randomly to each parcel.
B. The researcher's method	may be flawed because the different groups of parcels might differ systematically.

2. A clinical trial is carried out for a new cholesterol-lowering drug. The drug is given to 500 patients and a placebo given to another 500 patients, using random assignment of the patients.		
	How would you estimate the treatment effect of the drug?	
	○ A. It could be estimated by comparing the cholesterol levels of two random individuals in the treated group.	
	O B. It could be estimated as the difference in average cholesterol levels for the treated group and the untreated (control) group.	
	O. It could be estimated by comparing the cholesterol levels of one randomly chosen individual from each group.	
	O. It could be estimated by observing the average cholesterol level of all individuals from both groups over a period of time.	
	Suppose that you had data on the weight, age, and gender of each patient.	
	Could you use these data to improve your estimate? Explain.	
	O A. Data on the weight, age, and gender of each patient could not be used to improve the estimate since they will lead to multicollineari	
	O B. Data on the weight, age, and gender of each patient could be used to improve the estimate using the differences estimator with the	
	O. A regression with these additional regressors may produce a less accurate estimate because it considers these additional factors the	
	O. The regression may not produce a more accurate estimate because the additional information is not related to cholesterol.	
	Suppose that you had data on the cholesterol levels of each patient before he or she entered the experiment.	
	Could you use these data to improve your estimate? Explain.	
	○ A. The use of the additional data will result in a noncompliance with the experiment protocol.	
	OB. The data will not accurately demonstrate the person's genetic predisposition to high cholesterol.	
	○ C. The differences-in-differences estimator, which controls for individual-specific determinants of cholesterol levels that are constant over the differences of the difference of the di	
	O. The differences-in-differences estimator, which controls for individual-specific determinants of cholesterol levels that are constant or	
	Answers B.  It could be estimated as the difference in average cholesterol levels for the treated group and the untreated (control) group.	
	B.	
	Data on the weight, age, and gender of each patient could be used to improve the estimate using the differences estimator with these additional regressors.	
	D.	
	The differences-in-differences estimator, which controls for individual-specific determinants of cholesterol levels that are constant over the sample period, can be used.

3. Suppose that, in a randomized controlled experiment of the effect of an SAT preparatory course on SAT scores, the following results are reported:

	Treatment Group	Control Group
Average SAT score	1,244	1,205
Standard deviation of SAT score	92.1	97.1
Number of men	57	43
Number of women	43	57

There would be nonrandom assignment if men (or women) had different probabilities of being assigned to the treatment group and to the control group. Let $p_{Men}$ denote the probability that a male is assigned to the treatment group. Random assignment to a group means $p_{Men} = 0.5$ .  Calculate the $t$ -statistic for random assignment of a male to a group under the null hypothesis of $p_{Men} = 0.5$ at the 10% level of significance. $t$ -statistic =	Estimate the average treatment effect on test scores.
control group. Let $p_{Men}$ denote the probability that a male is assigned to the treatment group. Random assignment to a group means $p_{Men} = 0.5$ .  Calculate the $t$ -statistic for random assignment of a male to a group under the null hypothesis of $p_{Men} = 0.5$ at the 10% level of significance. $t$ -statistic =	Average treatment effect = points. (Enter your response as an integer.)
Calculate the $t$ -statistic for random assignment of a male to a group under the null hypothesis of $p_{Men} = 0.5$ at the 10% level of significance. $t$ -statistic =	There would be nonrandom assignment if men (or women) had different probabilities of being assigned to the treatment group and to the control group. 7.	Suppose we have a multiple regression equation as follows:
	$Y_i = \beta_0 + \beta_1 X_i + \beta_2 W_{1i} + + \beta_{1+r} W_{ri} + u_i, i = 1,, n,$
	where $X_i$ is a binary regressor, $W_{1i}W_{ri}$ are the control regressors, and $\beta_0$ , $\beta_1,,\beta_{1+r}$ are the intercept and the slope coefficients on the binary regressor and the control regressors, respectively.
	Which of the following statements correctly describe the features of a difference estimator with multiple regressors?
	☐ A. If W helps to explain the variation in Y, then including W reduces the standard error of the regression and, typically, the standard error
	$\square$ <b>B.</b> The control regressors should include experimental outcomes; i.e., $X_i$ is randomly assigned, given an experimental outcome.
	$\square$ <b>C.</b> If $W_i$ is a pretreatment characteristic and $X_i$ is randomly assigned, then $X_i$ is independent of $u_i$ and $W_i$ .
	□ D. The coefficients on the control variables do not have causal interpretations.
	Randomization in which the probability of assignment to the treatment group depends on one or more (1) is called randomization based on covariates.
	(1) Observable variables O experimental outcomes
	Answers A.  If $W$ helps to explain the variation in $Y$ , then including $W$ reduces the standard error of the regression and, typically, the standard error of $\hat{\beta}_1$ .  , C. If $W_i$ is a pretreatment characteristic and $X_i$ is randomly assigned, then $X_i$ is independent of $u_i$ and $W_i$ ., D. The coefficients on the control variables do not have causal interpretations.  (1) observable variables

9.	Consider a study to evaluate the effect on college student grades of dorm room Internet connections. In a large dorm, half the rooms are randomly wired for high-speed Internet connections (the treatment group), and final course grades are collected for all residents.
	Which of the following pose threats to internal validity?
	(i.) Midway through the year, all the male athletes move into a fraternity and drop out of the study. (Their final grades are not observed.)
	(ii.) Engineering students assigned to the control group put together a local area network so that they can share a private wireless Internet connection that they pay for jointly.
	(iii.) The art majors in the treatment group never learn how to access their Internet accounts.
	(iv.) The economics majors in the treatment group provide access to their Internet connection to those in the control group, for a fee.
	<ul><li>○ A. Only (ii) and (iv) due to partial compliance.</li></ul>
	Only (i) due to attrition and (iii) due to failure to follow protocol.
	Only (i), (ii), and (iv) pose threats to internal validity.
	O. All of the scenarios above pose threats to internal validity.
	Answer: C. Only (i), (ii), and (iv) pose threats to internal validity.
	ID: Exercise 13.5
10.	Small sample sizes in an experiment:
	O A. may pose a problem because the assumption that errors are normally distributed is dubious for experimental data.
	OB. do not raise threats to the validity of confidence intervals as long as heteroskedasticity-robust standard errors are used.
	O. may affect confidence intervals but not hypothesis tests.
	O. bias the estimators of the causal effect.
	Answer: A. may pose a problem because the assumption that errors are normally distributed is dubious for experimental data.
	ID: Test A Ex 13.2.3
11.	The following is <i>not</i> a threat to external validity:
	○ A. partial compliance with the treatment protocol.
	○ B. experimental participants are volunteers.
	○ C. the treatment being studied is not representative of the treatment that would be implemented more broadly.
	O. the experimental sample is not representative of the population of interest.
	Answer: A. partial compliance with the treatment protocol.
	ID: Test B Ex 13.2.1

۱۷.	1116 10	Howing estimation method should not be used to test for randomization when $\lambda_i$ is binary.
	O A.	Linear probability model (OLS) with heteroskedasticity-robust standard errors.
	○ В.	Probit.
	O C.	Logit.
	O D.	Linear probability model (OLS) with homoskedasticity-only standard errors.
	Answ	er: D. Linear probability model (OLS) with homoskedasticity-only standard errors.
	ID: Te	st B Ex 13.2.2
13.	Testing	for the random receipt of treatment:
	O A.	entails testing the hypothesis that the coefficients on $W_{1j},,W_{rj}$ are nonzero in a regression of $X_i$ on $W_{1j},,W_r$ .
	∩ B.	is not possible, in general.
		entails testing the hypothesis that the coefficients on $W_{1i},,W_{ri}$ are zero in a regression of $X_i$ on $W_{1i},,W_r$ .
		is not meaningful since the LHS variable is binary.
	<b>O D</b> .	To not mounting at office the Erio Variable to binary.
	Answ	er: C. entails testing the hypothesis that the coefficients on $W_{1i},,W_{ri}$ are zero in a regression of $X_i$ on $W_{1i},,W_r$ .
	ID: Te	st B Ex 13.2.3
14.	Which	of the following statements does not describe a possible threat to the internal validity of randomized control experiments?
	O A.	There is a threat to the internal validity if the population studied and the population of interest are not sufficiently similar to justify g
		There is a threat to the internal validity if the treatment is not assigned randomly, but instead is based in part on the characteristics
		There is a threat to the internal validity if subjects drop out of the study after being randomly assigned to the treatment or the contr
	O D.	There is a threat to the internal validity if individuals fail to follow completely the randomized treatment protocol.
	Which apply.)	of the following statements describe possible threats to the external validity of randomized control experiments? (Check all that
	□ A.	There is a threat to the external validity if turning a small, temporary experimental program into a widespread, permanent program
	□ В.	There is a threat to the external validity if the sample size is small as this raises threats to the validity of confidence intervals and h
	□ C.	There is a threat to the external validity if in experiments with human subjects, merely because the subjects are in an experiment $\mathfrak c$
	□ D.	There is a threat to the external validity if the policy or program of interest is not sufficiently similar to the program studied to permi
	Answ	ers A.  There is a threat to the internal validity if the population studied and the population of interest are not sufficiently similar to justify generalizing the results.
		A.  There is a threat to the external validity if turning a small, temporary experimental program into a widespread, permanent program might change the economic environment sufficiently that the results from the experiment cannot be generalized.  , D.
		There is a threat to the external validity if the policy or program of interest is not sufficiently similar to the program studied to permit generalizing the results.
	ID: Co	oncept Exercise 13.2.1

15.	Researchers studying the STAR data report anecdotal evidence that school principals were pressured by some parents to place their children in the small classes. Suppose that some principals succumbed to this pressure and transferred some children into the small classes.
	How would such transfers compromise the internal validity of the study?
	O A. The internal validity is compromised if the students who were transferred to the small classes differed systematically from the other
	O B. The internal validity is compromised if the transferred students tended to have higher incomes and more learning opportunities out
	O. The internal validity is compromised because the transfer compromises the control group of the experiment.
	O. Both (a) and (b) are true.
	Suppose that you had data on the original random assignment of each student before the principal's intervention.
	How could you use this information to restore the internal validity of the study?
	O A. It could be used as an instrument in a regression to restore internal validity because the original random assignment is correlated
	OB. It could not be used as an instrument in a regression to restore internal validity because the original random assignment is exogen
	O. It could be used as an instrument in a regression to restore internal validity because the original random assignment is not exogen
	O. It could be used as an instrument in a regression to restore internal validity because the original random assignment is exogenous
	Answers D. Both (a) and (b) are true.
	D.
	It could be used as an instrument in a regression to restore internal validity because the original random assignment is exogenous or uncorrelated with the regression error and is relevant or correlated with the actual assignment.
	ID: Review Concept 13.3

Table 1: Differences Estimates of Effect on Standardized Test Scores of Class Size Treatment Group

		Grade		
Regressor	K	1	2	3
Small class	13.51**	29.19**	19.67**	15.33**
	(2.48)	(2.88)	(2.79)	(2.32)
Regular size with aide	0.31	11.96	3.48	-0.29
	(2.27)	(2.65)	(2.54)	(2.27)
Intercept	918.04**	1039.39**	1157.81**	1228.51**
	(1.63)	(1.78)	(1.82)	(1.68)
Number of observations	5786	6379	6049	5967

*Note:* The dependent variable is the student's combined score on the math and reading portions of an achievement test. Standard errors are given in parentheses under the coefficients. \*\* The individual coefficient is statistically significant at the 1% significance level using a two-sided test.

Using the results in the table above, calculate the following for each grade: an estimate of the small class treatment effect, relative to the regular class; its standard error; and its 95% confidence interval. (For this exercise, ignore the results for regular classes with aides.)

For students in kindergarten:
The estimated small class treatment effect relative to being in a regular class is an increase of points on the test (Round your response to two decimal places.)
Standard error = . (Round your response to two decimal places.)
The 95% confidence interval = ( ). (Round your responses to two decimal places.)
For students in grade 1:
The estimated small class treatment effect relative to being in a regular class is an increase of points on the test (Round your response to two decimal places.)
Standard error = . (Round your response to two decimal places.)
The 95% confidence interval = ( ). (Round your responses to two decimal places.)
For students in grade 2:
The estimated small class treatment effect relative to being in a regular class is an increase of points on the test (Round your response to two decimal places.)
Standard error = . (Round your response to two decimal places.)
The 95% confidence interval = ( ). (Round your responses to two decimal places.)
For students in grade 3:
The estimated small class treatment effect relative to being in a regular class is an increase of points on the test (Round your response to two decimal places.)
Standard error = . (Round your response to two decimal places.)
The 95% confidence interval = ( ). (Round your responses to two decimal places.)

18.	Suppose that you have panel data from an experiment with $T = 2$ periods (so $t = 1, 2$ ). Consider the panel data regression model with fixed individual and time effects and individual characteristics $W_i$ that do not change over time, such as gender. Let the treatment
	be binary, so that $X_{it} = 1$ for $t = 2$ for the individuals in the treatment group and let $X_{it} = 0$ otherwise. Consider the population
	regression model:
	$Y_{it} = \alpha_i + \beta_1 X_{it} + \beta_2 (D_t \times W_i) + \beta_0 D_t + v_{it},$
	where $\alpha_i$ are individual fixed effects, $D_t$ is the binary variable that equals 1 if $t = 2$ and equals 0 if $t = 1$ , $D_t \times W_i$ is the product of $D_t$ and
	$W_i$ , and the $\alpha$ 's and $\beta$ 's are unknown coefficients. Let $\Delta Y_i = Y_{i2} - Y_{i1}$ .
	Write the above regression equation as a multiple regression equation with $\Delta Y_i$ as the dependent variable, which can be used for
	the differences-in-differences estimation (that is, in the form of Equation 13.6 from the text).
	$\Delta Y_i = $ . (Properly format your expression using the tools in the palette. Hover over tools to see keyboard shortcuts. E.g.,
	a subscript can be created with the _ character.)
	Arrayan O. O. V. O. W.
	Answer: $\beta_0 + \beta_1 X_i + \beta_2 W_i + u_i$

controlled experiment.

21. In a sharp regression discontinuity design:	
	$\bigcirc$ <b>A.</b> $X_i$ will in general be correlated with $\mu_i$ .
	O B. crossing the threshold influences receipt of the treatment but is not the sole determinant.
	○ C. the population regression line must be linear above and below the threshold.
	O. receipt of treatment is entirely determined by whether <i>W</i> exceeds the threshold.
	Answer: D. receipt of treatment is entirely determined by whether $W$ exceeds the threshold.
	ID: Test A Ex 13.4.5
22.	A repeated cross-sectional data set is:
	O A. a collection of cross-sectional data sets, where each cross-sectional data set corresponds to a different time period.
	O B. the same as a balanced panel data set.
	○ C. time series.
	O. what Card and Krueger used in their study of the effect of minimum wages on teenage employment.
	Answer: A. a collection of cross-sectional data sets, where each cross-sectional data set corresponds to a different time period.
	ID: Test B Ex 13.4.4
23.	Nuclear weapons testing releases large quantities of radioactive isotopes into the atmosphere, some of which are incorporated into biological tissues. The release stopped after the Partial Nuclear Test Ban Treaty in 1963, which prohibited atmospheric nuclear tests. Although, some countries that did not sign the treaty continued atmospheric nuclear weapons testing. A researcher wants to test the effect of the Partial Nuclear Test Ban Treaty, on the cancer rate, ( <i>Canrate</i> , measured as percentage of cancer patients in a country). He uses data from two randomly selected countries A and B from 1942 to 1996, such that country A is a signatory and country B is a non-signatory of the Partial Nuclear Test Ban Treaty. Country B continued atmospheric nuclear testing after 1963 until 1996. The researcher uses the data from country A as the treatment group and the data from country B as the control group.
	The average cancer rates calculated using the data from 1942 to 1963 in country A ( $\overline{Canrate}^{A, before}$ ) and country B ( $\overline{Canrate}^{B, before}$ ) are 12.12% and 16.17%, respectively. The average cancer rates calculated using the data from 1964 to 1985 in countries A ( $\overline{Canrate}^{A, after}$ ) and B ( $\overline{Canrate}^{B, after}$ ) are 4.61% and 9.91%, respectively.
	The differences-in-differences estimator of the causal effect of the treaty is %.
	(Round your answer to two decimal places. Enter a minus sign if your answer is negative.)
	The researcher isolates data for two specific years, 1957 and 1975, for countries A and B and estimates the following regression equation:
	$\widehat{Canrate}_{it} = 0.13 - 0.015X_{it} - 0.018G_i - 0.036D_t$ , (i = A, B and t = 1957, 1975)
	(0.013) (0.007) (0.0016) (0.0021)
	where $G$ is a binary variable that takes the value 1 if the data is from the treatment group and 0 otherwise, $D$ is a binary variable that takes the value 1 if the data is for 1975 and 0 if the data is for 1957, and $X = (G \times D)$ . Standard errors are given in parentheses.
	The differences-in-differences estimator of the causal effect of the treaty is
	(Round your answer to three decimal places. Enter a minus sign if your answer is negative.)

## 27. Suppose the population regression equation is given by:

$$Y_i = \beta_{0i} + \beta_{1i} X_i + u_i.$$

Because  $\beta_{1i}$  varies from one individual to the next in the population and the individuals are selected from the population at random,  $\beta_{1i}$  is a random variable that, just like  $u_i$ , reflects unobserved variation across individuals.

Which of the following is correct? (*Hint:* Use the definition of the covariance and that, because the actual treatment  $X_i$  is random,  $\beta_{1i}$  and  $X_i$  are independently distributed.)

$$\frac{\text{Cov}\left\{\beta_{1i}X_{i},\,X_{i}\right\}}{\sigma_{\chi}^{2}} = \frac{\text{Cov}\left\{\beta_{0i}+\beta_{1i}X_{i},\,X_{i}\right\}}{\sigma_{\chi}^{2}} = E\left\{\beta_{1i}\right\} = \widehat{\beta_{1}}.$$

$$\bigcirc \mathbf{C.} \quad \text{cov}\left(\beta_{1i}X_i, X_i\right) = E\left(\beta_{1i}\right)\sigma_X^2.$$

O. All of the above.

Answer: D. All of the above.

ID: Exercise 13.9

28.	Suppose that a researcher wants to study the effect of doing an optional online economics problem set ( $PS = 1$ if a student does the problem set, and $PS = 0$ otherwise) on the grades students receive on their final economics test ( $Grade$ , expressed as a percentage). She randomly selects 250 students for her study and then assigns them randomly to the treatment group or the control group in equal numbers. The population under consideration is heterogeneous, so each student has his or her own causal effect, which is the difference in that student's potential test grades when the problem set is solved and when it is not. Suppose that students randomly decide whether or not to do the optional online problem set. The population regression equation can be written as:
	$Grade = \beta_{0i} + \beta_{1i} PS_i + u_i,$
	where $\beta_{1i}$ varies from one student to the next in the population and the students are selected from the population at random. The sample
	covariance between <i>PS</i> and <i>Grade</i> was calculated to be 6.94, the variance of <i>PS</i> was calculated to be 3.95, and the variance of <i>Grade</i> was calculated to be 3.24.
	The OLS estimator which is a consistent estimator of the average causal effect of a randomly selected student is
	(Round your answer to two decimal places.)
	Suppose that the causal effect is estimated by instrumental variables regression of $Grade$ on $PS$ using ownership of a laptop ( $L = 1$ if the student owns a laptop, and $L = 0$ otherwise) as an instrument. The incidence of owning a laptop is random among the students. Assume that the instrument is exogenous and relevant.
	The sample covariance between $Grade$ and $L$ is 6.84, the sample covariance between $PS$ and $L$ is 4.14, and the sample covariance between $Grade$ and $PS$ is 6.94.
	The TSLS estimator which is a consistent estimator of the local average treatment effect (LATE) is
	(Round your answer to two decimal places.)
	Suppose the laptops that the students own were randomly assigned by the university to exactly half the student population. Owning a laptop does not have any effect on the decision to do the problem set and consequently, the effect of doing the problem set on the grade the student receives is 1.39. But, not owning a laptop has an effect of $-0.52$ on the decision to do the problem set and consequently, the effect of doing the problem set on the grade the student receives is 1.25.
	The average treatment effect is
	(Round your answer to two decimal places.)

	th of the following statements are correct in describing the threats to internal and external validity that are or are not faced uasi-experiments? (Check all that apply.)
	Checking for systematic differences between the treatment and control groups to test for failure of randomization is not possible as some factors in the error term which could be related to the treatment level X are unobserved.
E	3. Experimental effects such as the Hawthorne effect in a quasi-experiment are similar to such effects in a true experiment, but attrition does not occur in a quasi-experiment as it is not possible for individuals to drop out of such studies.
	As special events create the as-if randomness at the core of a quasi-experimental study, they can result in other special features that never threaten external validity.
	<ol> <li>Just because an instrument is randomly determined or as-if randomly determined in a quasi-experiment does not necessarily mean it is exogenous.</li> </ol>
	se of IV regression with heterogeneous causal effects, the two stage least square estimator (TSLS) is a (1)nator of the weighted average of the individual causal effects also known as the local average treatment effect (LATE).
In wh	nich of the following cases is the local average treatment effect not equal to the average treatment effect?
O A	. When an individual's decision to receive treatment depends on the effectiveness of the treatment for that individual.
O E	3. When the heterogeneity in the treatment effect and heterogeneity in the effect of the instrument are uncorrelated.
$\bigcirc$ c	. When the instrument affects each individual equally.
0	When the treatment effect is the same for all individuals.
	oose two researchers use two different instruments that are both valid (i.e., both are relevant and exogenous) to estimate the age causal effect in heterogeneous populations.
In lar	rge samples, the researchers would obtain (2) TSLS estimators of the average causal effect.
(1)	inconsistent (2) the same consistent different
Ans	swers A.
	Checking for systematic differences between the treatment and control groups to test for failure of randomization is not possible as some factors in the error term which could be related to the treatment level X are unobserved.
	, D.  Just because an instrument is randomly determined or as-if randomly determined in a quasi-experiment does not necessarily mean it is exogenous.
	(1) consistent
	A. When an individual's decision to receive treatment depends on the effectiveness of the treatment for that individual.
