1. Consider a random variable Y. What is the difference between the sample average $\overline{Y}$ and the population mean?

   ○ **A.** The population mean is a true measure of the central tendency of the distribution of Y whereas the sample average $\overline{Y}$ is an estimato

   ○ **B.** Both the population mean and the sample average $\overline{Y}$ are estimators of the central tendency of the distribution of Y.

   ○ **C.** Both the population mean and the sample average $\overline{Y}$ are true measures of the central tendency of the distribution of Y.

   ○ **D.** The sample average $\overline{Y}$ is a true measure of the central tendency of the distribution of Y whereas the population mean is an estimato

   Answer: A.
   The population mean is a true measure of the central tendency of the distribution of Y whereas the sample average $\overline{Y}$ is an estimator of the population mean.

2. What is the difference between an estimator and an estimate?

  ○ **A.** Both an estimator and an estimate are numerical values computed using data from a specific sample.

  ○ **B.** An estimate is a function of a sample of data to be drawn randomly from a population whereas an estimator is the numerical value o

  ○ **C.** Both an estimator and an estimate are functions of a sample of data to be drawn randomly from a population.

  ○ **D.** An estimator is a function of a sample of data to be drawn randomly from a population whereas an estimate is the numerical value o

  Determine whether the following are examples of estimators, estimates or neither.

  A. The mean value of random variable Y in a population. (1) ⎯⎯⎯⎯⎯⎯

  B. The sample average is 92.1. (2) ⎯⎯⎯⎯⎯

  C. The sample variance is 9.2. (3) ⎯⎯⎯⎯⎯

  D. The sample variance is $\widehat{\sigma_X}$. (4) ⎯⎯⎯⎯⎯

  E. The variance of random variable Z in a population. (5) ⎯⎯⎯⎯⎯

  Answers D.
        An estimator is a function of a sample of data to be drawn randomly from a population whereas an estimate is the numerical
        value of the estimator when it is actually computed using data from a specific sample.

  (1) neither

  (2) estimate

  (3) estimate

  (4) estimator

  (5) neither

3. Suppose random variable X follows a normal distribution with mean 10 and variance 16. Consider random samples of different sizes from that population to answer the following questions.

Consider a sample of size n = 10. Download the data attached in the data table and use it to construct your response   .

For n = 10, the sample mean = [   ]

(*Round your response to three decimal places*)

Consider a sample of size n = 100. Download the data attached in the data table and use it to construct your response   .

For n = 100, the sample mean = [   ]

(*Round your response to three decimal places*)

Consider a sample of size n = 999. Download the data attached in the data table and use it to construct your response   .

For n = 999, the sample mean = [   ]

(*Round your response to three decimal places*)

How can you relate your answers above to the law of large numbers?

- ○ **A.** The sample size has no effect on the sample mean.
- ○ **B.** As the sample size increases, the positive distance between the sample mean and the population mean increases.
- ○ **C.** As the sample size increases, the sample mean approaches the population mean.
- ○ **D.** The sample mean is equal to the population mean regardless what the sample size is.

5. Observe that for a random variable Y that takes on values 0 and 1, the expected value of Y is defined as follows:

$$E(Y) = 0 \times \Pr(Y = 0) + 1 \times \Pr(Y = 1)$$

and the variance of Y is

$$var(Y) = E\left[(Y - \mu_y)^2\right] = (0 - p)^2 \times \Pr(Y = 0) + (1 - p)^2 \times \Pr(Y = 1) = p^2(1 - p) + (1 - p)^2 p = p(1 - p)$$

Now, suppose that X is a Bernoulli random variable with success probability $\Pr(X = 1) = p$ and let $Y_1,...,Y_n$ be i.i.d. draws from this distribution. Also, let $\hat{p}$ be the fraction of successes (1s) in this sample.

Use the information above to answer the following questions.

Show that $\hat{p} = \bar{Y}$.

$$\hat{p} = \#\left(\frac{\quad (1) \quad}{n} =\right) \frac{\#(Y_i = \quad (2) \quad)}{n} = \frac{\Sigma_{i=1}^n Y_i}{n} = \bar{Y}$$

Show that $\hat{p}$ is an unbiassed estimator of p.

$$E\left(\hat{p}\right) = E\left(\frac{\Sigma_{i=1}^n Y_i}{n}\right) = \frac{1 \quad (5)}{E(\underline{\quad (3) \quad})} \frac{\Sigma_{i=1}^n}{} = \frac{1 \quad (6)}{} \Sigma_{i=1}^n (4) \underline{\qquad} = p$$

Show that $var(\hat{p}) = \dfrac{p(1-p)}{n}$.

$$var\left(\hat{p}\right) = var\left(\frac{\Sigma_{i=1}^n Y_i}{n}\right) = \frac{1 \quad (9)}{var(\underline{(7)})} \frac{\Sigma_{i=1}^n}{} = \frac{1 \quad (10)}{} \Sigma_{i=1}^n (8) \underline{\qquad} = \frac{p(1-p)}{n}$$

6. Follow the steps below to show that the sample variance is an unbiased estimator of the population variance when $Y_1, ..., Y_n$ are i.i.d. with mean μ_Y and variance σ_Y^2.

Step 1. Use the following equation to show that $E\left[(Y_i - \bar{Y})^2\right] = \text{var}(Y_i) - 2\text{cov}(Y_i, \bar{Y}) + \text{var}(\bar{Y})$. For random variables X and Y,

$$\text{var}(aX + bY) = a^2\sigma_X^2 + 2ab\sigma_{XY} + b^2\sigma_Y^2$$

First observe that $E\left[(Y_i - \bar{Y})^2\right] = E\left\{\left[(Y_i - \mu_Y) - (\bar{Y} - \mu_Y)\right]^2\right\}$ by adding and subtracting μ_Y inside the expression.

Expand this to get,

$$= E[(Y_i - \text{(1)} \underline{\hspace{2cm}})^2 - \boxed{}(Y_i - \text{(2)} \underline{\hspace{2cm}})(\text{(3)} \underline{\hspace{2cm}} - \mu_Y) +$$

$(\bar{Y} - \mu_Y)^2]$

Distributing the expectation,

$$= E[(Y_i - \mu_Y)^2] - 2E[(Y_i - \mu_Y)(\bar{Y} - \mu_Y)] + E[(\bar{Y} - \mu_Y)^2]$$

Consider the last expression above. This is equivalent term by term to

$$= \text{(4)} \underline{\hspace{2cm}} - 2\,\text{(5)} \underline{\hspace{2cm}} + \text{(6)} \underline{\hspace{2cm}}$$

Therefore, $E\left[(Y_i - \bar{Y})^2\right] = \text{var}(Y_i) - 2\text{cov}(Y_i, \bar{Y}) + \text{var}(\bar{Y})$. Call this result (A).

Now, use the following equation to show that $\text{cov}(\bar{Y}, Y_i) = \dfrac{\sigma_Y^2}{n}$. For random variables X, V and Y,

$$\text{cov}(a + bX + cV, Y) = b\sigma_{XY} + c\sigma_{VY}$$

First, observe that by definition of covariance,

$$\text{cov}(\bar{Y}, Y) = \text{(7)} \underline{\hspace{2cm}}$$

By definition of $\bar{Y}$, this is equivalent to

$$= E\left[\left(\frac{\Sigma_{j=1}^n Y_j}{n} - \mu_Y\right)(Y_i - \mu_Y)\right] = E\left[\left(\frac{\Sigma_{j=1}^n (Y_j - \mu_Y)}{n}\right)(Y_i - \mu_Y)\right]$$

Distributing the expectation,

$$= \text{(8)} \underline{\hspace{2cm}} E\,[\text{(9)} \underline{\hspace{2cm}}] + \text{(10)} \underline{\hspace{2cm}} \sum_{j \neq i} E\left[(Y_j - \mu_Y)(Y_i - \mu_Y)\right]$$

Consider the last expression above. This is equivalent term by term to

$$= \frac{1}{n}\,\text{(11)} \underline{\hspace{2cm}} + \frac{1}{n}\sum_{j \neq i}\,\text{(12)} \underline{\hspace{2cm}} = \frac{\sigma_Y^2}{n}$$

Therefore, $\text{cov}(\bar{Y}, Y_i) = \dfrac{\sigma_Y^2}{n}$. Call this result (B).

Let s_Y^2 denote the sample variance. Use results A and B to show that $E\left(s_Y^2\right) = \sigma_Y^2$.

First, observe that by definition of sample variance,

$$E\left(s_Y^2\right) = E\,[\text{(13)} \underline{\hspace{2cm}} \sum_{i=1}^n \text{(14)} \underline{\hspace{2cm}}]$$

Using result **A**, this becomes

$$= \frac{1}{n-1} \sum_{i=1}^{n} E\left[\left(Y_i - \bar{Y}\right)^2\right] = \frac{1}{n-1} \sum_{i=1}^{n} [(15) \underline{\hspace{3cm}}]$$

Using result **B**, this simplifies to

$$= \frac{1}{n-1} \sum_{i=1}^{n} [\sigma_Y^2 - 2 \times (16) \underline{\hspace{2cm}} + \frac{\sigma_Y^2}{n}]$$

Finally,

$$= \frac{1}{n-1} \sum_{i=1}^{n} \left(\frac{n-1}{n} \sigma_Y^2\right) = \sigma_Y^2$$

Since $E\left(s_Y^2\right) = \sigma_Y^2$, the sample variance is an unbiased estimator of the population variance.

ID: Exercise 3.18

7. Let $Y_1, ..., Y_n$ be i.i.d with mean μ_Y and variance σ_Y^2.

$\bar{Y}$ is an unbiased estimator of μ_Y. Is $\bar{Y}^2$ an unbiased estimator of μ_Y^2?

First, note that for a random variable X

$$\text{var}(X) = E(X^2) - E(X)^2 = E(X^2) - \mu_X^2 \text{ and } E(X_i X_j) = \mu_X^2 \text{ for } i \neq j.$$

So,

$$E(\bar{Y}^2) = E\left[\left(\frac{1}{n}\sum_{i=1}^{n} Y_i\right)^2\right] = \frac{1}{n^2}\sum_{i=1}^{n} E(Y_i^2) + \frac{1}{n^2}\sum_{i=1}^{n}\sum_{j \neq i} E(Y_i Y_j) = (1) \underline{\hspace{2cm}} + (2) \underline{\hspace{2cm}} (3) \underline{\hspace{2cm}}$$

Hence,

A. Yes, $\bar{Y}^2$ is an unbiased estimator of μ_Y^2.

B. No, $\bar{Y}^2$ is not an unbiased estimator of μ_Y^2.

$\bar{Y}$ is a consistent estimator of μ_Y. Is $\bar{Y}^2$ a consistent estimator of μ_Y^2?

$$E(\bar{Y}^2) = E\left[\left(\frac{1}{n}\sum_{i=1}^{n} Y_i\right)^2\right] = \frac{1}{n^2}\sum_{i=1}^{n} E(Y_i^2) + \frac{1}{n^2}\sum_{i=1}^{n}\sum_{j \neq i} E(Y_i Y_j) = \mu_Y^2 + \frac{1}{n}\sigma_Y^2$$

Hence,

A. Yes, $\bar{Y}^2$ is a consistent estimator of μ_Y^2.

B. No, $\bar{Y}^2$ is not a consistent estimator of μ_Y^2.

10. Suppose K_1, K_2, and K_3 are three independent and unbiased estimators of μ. Their variances are in the ratio of 3:8:2.

Z_1, Z_2 and Z_3 are three other estimators of μ such that:

$$Z_1 = \frac{\left(5K_1 + K_2 + K_3\right)}{7},$$

$$Z_2 = \frac{\left(K_1 + 5K_2 + K_3\right)}{7},$$

$$Z_3 = \frac{\left(K_1 + K_2 + 5K_3\right)}{7}.$$

Which among Z_1, Z_2, and Z_3 are unbiased estimators of μ?

- **A.** Z_1, Z_2, and Z_3 are all unbiased.
- **B.** Z_2 and Z_3 are unbiased but Z_1 is biased.
- **C.** Z_1 and Z_3 are unbiased but Z_2 is biased.
- **D.** Z_1, Z_2, and Z_3 are all biased.

Which among Z_1, Z_2, and Z_3 would be the best estimator for μ?

- **A.** Both Z_1 and Z_2 could be chosen since they are unbiased and have the least variances.
- **B.** Sufficient information is not provided to determine which estimator would be the best.
- **C.** Z_3 should be chosen since it is both unbiased and has the least variance.
- **D.** Z_2 should be chosen since it is both unbiased and consistent.

Answers A. Z_1, Z_2, and Z_3 are all unbiased.

C. Z_3 should be chosen since it is both unbiased and has the least variance.

11. In a survey of 400 likely voters, 216 responded that they would vote for the incumbent and 184 responded that they would vote for the challenger. Let p denote the fraction of all likely voters who preferred the incumbent at the time of the survey, and let $\hat{p}$ be the fraction of survey respondents who preferred the incumbent.

Using the survey results, the estimated value of $\hat{p}$ is [____]. (*Round your response to four decimal places.*)

Using $\hat{p}(1 - \hat{p})/n$ as the estimator of the variance of $\hat{p}$, the standard error of the estimator is [____]. (*Round your response to four decimal places.*)

The p-value for the test $H_0: p = 0.5$ versus $H_1: p \neq 0.5$ is [____]. (*Round your response to three decimal places.*)

The p-value for the test $H_0: p = 0.5$ versus $H_1: p > 0.5$ is [____]. (*Round your response to three decimal places.*)

Why do the p-values for $H_0: p = 0.5$ versus $H_1: p \neq 0.5$ and $H_0: p = 0.5$ versus $H_1: p > 0.5$ differ?

○ **A.** $H_0: p = 0.5$ versus $H_1: p > 0.5$ is a one-sided test and the p-value is the area under the standard normal distribution to the left of th

○ **B.** $H_0: p = 0.5$ versus $H_1: p \neq 0.5$ is a two-sided test and the p-value is the area in the tails of the standard normal distribution outside

○ **C.** $H_0: p = 0.5$ versus $H_1: p \neq 0.5$ is a one-sided test and the p-value is the area under the standard normal distribution to the right of t

○ **D.** $H_0: p = 0.5$ versus $H_1: p > 0.5$ is a two-sided test and the p-value is the area in the tails of the standard normal distribution outside

Did the survey contain statistically significant evidence that the incumbent was ahead of the challenger at the time of the survey?

○ **A.** For the test $H_0: p = 0.5$ versus $H_1: p > 0.5$, we can reject the null hypothesis at the 5% significance level. The p-value is less than 0 survey.

○ **B.** For the test $H_0: p = 0.5$ versus $H_1: p \neq 0.5$, we can reject the null hypothesis at the 5% significance level. The p-value is less than 0 survey.

○ **C.** For the test $H_0: p = 0.5$ versus $H_1: p > 0.5$, we cannot reject the null hypothesis at the 5% significance level. The p-value is larger t the survey.

○ **D.** For the test $H_0: p = 0.5$ versus $H_1: p \neq 0.5$, we cannot reject the null hypothesis at the 5% significance level. The p-value is larger t the survey.

Answers 0.540

0.0249

0.108

0.054

B.
$H_0: p = 0.5$ versus $H_1: p \neq 0.5$ is a two-sided test and the p-value is the area in the tails of the standard normal distribution outside ± the calculated t-statistic.

C.
For the test $H_0: p = 0.5$ versus $H_1: p > 0.5$, we cannot reject the null hypothesis at the 5% significance level. The p-value is larger than 0.05. The test suggests that the survey did not contain statistically significant evidence that the incumbent was ahead of the challenger at the time of the survey.

17. Suppose a survey of a random sample of 100 smokers, conducted by the Department of Health, suggests that the mean number of cigarettes a person smokes in a day in Smokelandia ($\bar{Y}$) is 2.58 and the standard deviation (s_Y) is 0.58. The Department of Health is concerned about the results of the survey and wants to test whether the mean number of cigarettes a person smokes in a day is 2.51 or not.

The test statistic associated with the above test is [____].

(*Round your answer to two decimal places.*)

If the Department of Health uses a 5% significance level, the test statistic suggests that we (1) _____ the hypothesis that the mean number of cigarettes a person smokes in a day is 2.51.

Suppose the Department of Health decides to reject the null hypothesis (H_0) if $|\bar{Y} - 2.51| > 0.08$.

The size of the above test is [____].

(*Round your answer to two decimal places.*)

If $\mu = 2.68$, the power of the above test is [____].

19. Suppose we want to test whether true population parameter θ equals a certain number. Consider the following hypothesis test:

$$H_0: \theta = c$$
$$H_1: \theta \neq c$$

Where H_0 is the null hypothesis, H_1 is the alternative hypothesis, and c a constant. Let $\bar{\theta}$ be an estimator of θ.

What role does the central limit theorem play in the construction of confidence intervals?

○ **A.** The central limit theorem allows us to directly compute the true value of θ.

○ **B.** To construct a confidence interval for θ, it is necessary to know the sampling distribution of $\bar{\theta}$ under the null hypothesis. If the sam small.

○ **C.** To construct a confidence interval for θ, it is necessary to know the sampling distribution of $\bar{\theta}$ under the null hypothesis. If the sam large.

○ **D.** The central limit theorem plays no role in the construction of confidence intervals.

Answer: C.
    To construct a confidence interval for θ, it is necessary to know the sampling distribution of $\bar{\theta}$ under the null hypothesis. If the sampling distribution is unknown, the central limit theorem says that it can be approximated by a normal distribution when the sample size n is sufficiently large.

20. Let Y be a random variable. Consider the following hypothesis test:

$$H_0: E(Y) = \mu_{Y, 0}$$
$$H_1: E(Y) \neq \mu_{Y, 0}$$

Where H_0 is the null hypothesis and H_1 is the alternative hypothesis.

Which of the following statements are true about the null and alternative hypothesis? *(Check all that apply.)*

☐ **A.** Hypothesis testing entails using data to provide sufficient evidence against the null hypothesis and in favor of the alternative hypot

☐ **B.** The null hypothesis is that the population mean $E(Y)$ takes on a specific value whereas the alternative hypothesis specifies what is

☐ **C.** Hypothesis testing entails using data to provide sufficient evidence against both the null and alternative hypothesis.

☐ **D.** If the null hypothesis is accepted the statistician declares it to be true and the alternative false. If the null hypothesis is rejected the

☐ **E.** Hypothesis testing entails using data to provide sufficient evidence in favor of both the null and alternative hypothesis.

Determine whether the following illustrate a one–sided alternative hypothesis or a two–sided alternative hypothesis.

1. $H_0: E(Y) = \mu_{Y, 0}$ vs. $H_1: E(Y) \leq \mu_{Y, 0}$. This example illustrates a (1) _____ alternative hypothesis.

2. $H_0: E(Y) = \mu_{Y, 0}$ vs. $H_1: E(Y) \neq \mu_{Y, 0}$. This example illustrates a (2) _____ alternative hypothesis.

3. $H_0: E(Y) = \mu_{Y, 0}$ vs. $H_1: E(Y) > \mu_{Y, 0}$. This example illustrates a (3) _____ alternative hypothesis.

A (4) _____ alternative hypothesis states the value is *either* greater than or less than $\mu_{Y, 0}$ but not both, whereas a

(5) _____ alternative hypothesis simply states the value is not equal to $\mu_{Y, 0}$.

Match the hypothesis testing terminology to its definition.

1. The probability that the test correctly rejects the null hypothesis when the alternative is true. (6) _____

2. The prescribed rejection probability of a statistical hypothesis test when the null hypothesis is true. (7) _____

3. The value of the statistic for which the test just rejects the null hypothesis at the given significance level. (8) _____

4. The probability that the test incorrectly rejects the null hypothesis when it is true. (9) _____

(1) ○ one-sided   (2) ○ two-sided   (3) ○ one-sided   (4) ○ one-sided   (5) ○ one-sided
    ○ two-sided   ○ one-sided   ○ two-sided   ○ two-sided   ○ two-sided

(6) ○ Power of the test   (7) ○ Power of the test   (8) ○ Power of the test   (9) ○ Power of the test
    ○ Significance level   ○ Significance level   ○ Significance level   ○ Significance level
    ○ Critical value   ○ Critical value   ○ Critical value   ○ Critical value
    ○ Size of the test   ○ Size of the test   ○ Size of the test   ○ Size of the test

Answers A.
Hypothesis testing entails using data to provide sufficient evidence against the null hypothesis and in favor of the alternative hypothesis.
, B.
The null hypothesis is that the population mean $E(Y)$ takes on a specific value whereas the alternative hypothesis specifies what true if the null hypothesis is not.

(1) one-sided

(2) two-sided

(3) one-sided

(4) one-sided

(5) two-sided

21. Let Y be a random variable. Suppose you are interested in estimating the population mean, $E(Y)$.

Which of the following statements about confidence intervals and hypotheses tests are true? *(Check all that apply.)*

☐ **A.** A confidence interval defines a rejection rule, at a specified significance level, for all possible values of the population mean, $E(Y)$,

☐ **B.** A confidence interval summarizes the set of hypotheses about the population mean, $E(Y)$, you can and cannot reject at a given sig

☐ **C.** A confidence interval defines a rejection rule, at a specified significance level, for only one possible value of the population mean,

☐ **D.** A single hypothesis test about the population mean, $E(Y)$, contains more information than a confidence interval.

Answer: A.
A confidence interval defines a rejection rule, at a specified significance level, for all possible values of the population mean, $E(Y)$, whereas a single hypothesis test is a rejection rule for only one possible value of the population mean.
, B.
A confidence interval summarizes the set of hypotheses about the population mean, $E(Y)$, you can and cannot reject at a given significance level.

22. Suppose a researcher believes that the average height of female students in a large local high school is 140 cm. The researcher wants to construct an interval that contains the true average height of all female students in the local high school with a certain prespecified probability. The researcher selects 36 female students at random from the high school. The distribution of heights is known to follow a normal distribution.

The given table shows the data she collected (in cm).

140	146	141	140	135	139
142	146	129	138	147	136
143	140	140	149	134	140
138	139	142	142	143	145
138	140	144	138	145	135
143	140	135	142	146	137

The average height of the female students in the given sample is [   ] cm.

The sample standard deviation is [   ] cm.

(*Round your answers to two decimal places.*)

The standard error of the sample mean height is [   ] cm.

The margin of error in calculating a 95% confidence interval for the average height of all female students in the local high school is [   ] cm.

(*Round your answers to two decimal places.*)

The 95% confidence interval for the average height of all female students in the local high school, μ_X, is: ([   ] , [   ]).

(*Round your answers to two decimal places.*)

25. An efficiency manager is evaluating the quality of sportswear manufactured by two brands - A and B. She wishes to test whether the difference between the mean number of faulty pieces supplied by the brands in each of their consignments is zero or not. For this, the manager collects data from the two brands. Suppose that the mean number of faulty pieces supplied by the brands are independent of each other.

Let n denote the number of consignments for which the data was collected, $\bar{X}$ denote the sample mean of the number of faulty pieces supplied per consignment by each brand, and S denote the sample standard deviation in the number of faulty pieces supplied per consignment by each brand. The given table shows the data collected.

Brand	n	$\bar{X}$	S
A	110	15.21	11.2
B	85	10.11	14.1

The manager's null hypothesis would be that the difference between the mean number of faulty pieces supplied per consignment by brands A and B is (1) _____ .

The manager's alternative hypothesis would be that the difference between the mean number of faulty pieces supplied per consignment by brands A and B is (2) _____ .

The standard error of the difference between the sample means is: [   ] .

(*Round your answer to two decimal places.*)

The *t*-statistic for testing the null hypothesis is [   ] .

(*Round your answer to two decimal places.*)

Given the value of the *t*-statistic, for a prespecified 1% level of significance, we (3) _____ the null hypothesis.

27. Suppose you have a binary randomized controlled experiment designed to measure the causal effect of X on Y. Let the control group be identified by $X = 0$ and the treatment group by $X = 1$.

The differences–of–means estimator, denoted by $E(Y|X = 1) - E(Y|X = 0)$, is an estimator of the causal effect of X on Y because the differences–of–means estimator estimates:

○ **A.** the change in the expectation of Y as result of an observation being in the treatment group as opposed to the control group.

○ **B.** the expectation of Y for observations within the treatment group.

○ **C.** the expectation of Y for observations within the control group.

○ **D.** All of the above.

Answer: A.
the change in the expectation of Y as result of an observation being in the treatment group as opposed to the control group.

28. Grades on a standardized test are known to have a mean of 1020 for students in the United States. The test is administered to 467 randomly selected students in Florida; in this sample, the mean is 1033.26 and the standard deviation (s) is 110.16.

The 95% confidence interval for the average test score for Florida students is (1023.27 , 1043.25). (*Round your responses to two decimal places.*)

Is there statistically significant evidence that Florida students perform differently than other students in the United States?

The 95% confidence interval for the average test score for Florida students (1) __does not include__ $\mu = 1020$, so the null hypothesis that $\mu = 1020$ (that Florida students have the same average performance as other students in the United States) (2) __can be rejected__ at the 5% level.

Another 517 students are selected at random from Florida. They are given a 3-hour preparation course before the test is administered. Their average test score is 1039.38 with a standard deviation of 96.90.

The 95% confidence interval for the change in average test score associated with the prep course is (-6.90 , 19.14). (*Round your responses to two decimal places.*)

Is there statistically significant evidence that the prep course helped?

- ○ **A.** Yes, because the 95% confidence interval for the change in average test score associated with the prep course includes $\mu_{prep} - \mu$,
- ○ **B.** Yes, because the 95% confidence interval for the change in average test score associated with the prep course does not include μ
- ● **C.** No, because the 95% confidence interval for the change in average test score associated with the prep course includes $\mu_{prep} - \mu_n$
- ○ **D.** No, because the 95% confidence interval for the change in average test score associated with the prep course does not include μ_{l}

The original 467 students are given the prep course and then are asked to take the test a second time. The average change in their test scores is 9.18 points, and the standard deviation of the change is 61.2 points.

Let X denote the change in the test score. The 95% confidence interval for the change in average test scores (μ_X) is (3.63 , 14.73). (*Round your responses to two decimal places.*)

Is there statistically significant evidence that students will perform better on their second attempt after taking the prep course?

- ○ **A.** Yes, because the 95% confidence interval for the change in average test scores does not include $\mu_X = 9.18$.
- ○ **B.** No, because the 95% confidence interval for the change in average test scores includes $\mu_X = 9.18$.
- ○ **C.** No, because the 95% confidence interval for the change in average test scores includes $\mu_X = 0$.
- ● **D.** Yes, because the 95% confidence interval for the change in average test scores does not include $\mu_X = 0$.

(1) ○ does not include   (2) ○ can be rejected
    ○ includes   ○ cannot be rejected

ID: Empirical Exercise 3.1

30. Open the Excel data set, <u>CPS92_08</u>[1]. A detailed description of the data is given in the file, <u>CPS92_08_Description</u>[2]. The Excel file is very large and we do not need to work with such a large data set at this point. Thus, take the first 300 observations for 1992 (cells A2:E301) and the first 300 observations for 2008 (cells A7607:E7906). Suggestion: copy the larger data set to another worksheet and then delete the cells that are not needed. Using this smaller version of CPS92_08 answer the following questions:

The mean for the average hourly earnings (*AHE*) in 1992 and 2008 are, respectively:

○ **A.** $10.85 and $17.88

○ **B.** $11.63 and $18.98

○ **C.** $12.09 and $19.12

○ **D.** $18.98 and $11.63

The 95% confidence interval for the population mean of *AHE* in 1992 is

○ **A.** 11.01 - 13.02

○ **B.** 10.85 - 12.04

○ **C.** 11.45 - 12.74

○ **D.**   9.22 - 11.88

The 95% confidence interval for the population mean of *AHE* in 2008 is

○ **A.** 18.15 - 21.05

○ **B.** 17.50 - 22.10

○ **C.** 18.02 - 20.22

○ **D.** 17.55 - 20.25

The Consumer Price Index (CPI) was 215.2 in 2008. The CPI was 140.3 in 1992. Convert the *AHE* in 1992 to 2008 dollars. That is, increase *AHE* in 1992 to what they would be in 2008 based solely on inflation. The mean of *AHE* in 1992 expressed in 2008 dollars is.

○ **A.** $18.95

○ **B.** $17.55

○ **C.** $19.06

○ **D.** $18.55

Get the difference in the means of *AHE* in 2008 and 1992 adjusted for inflation. In other words, get the difference in *AHE*s when both are expressed in 2008 dollars.
Use a two-tailed test to determine whether the population mean of *AHE* adjusted for inflation is different in 1992 and 2008 at the 5% level of significance. Use equation 3.19 in your text to compute the standard error of the difference in means. The null hypothesis is : H_0:
$MeanAHE_{2008} - MeanAHE_{aj,1992} = 0$

○ **A.** The difference, $0.57; it's NOT statistically different from 0 at the 5% level

○ **B.** The difference, $6.96; it's statistically different from 0 at the 5% level

○ **C.** The difference, $0.57; it's statistically different from 0 at the 5% level

○ **D.** The difference, $6.96; it's NOT statistically different from 0 at the 5% level

The 95% confidence interval for the population difference in the means of *AHE* in 2008 and 1992 used in part (5) is:

○ **A.**   0.20 - 0.95

○ **B.**   -0.18 - 1.32

○ **C.** - 0.91 - 2.05

○ **D.** -0.05 - 1.05

The difference in the population mean of *AHE* for those with and without a bachelor's degree in 2008 is

A. $5.87

B. $6.97

C. $0.52

D. $4.87

Obtain the 95% confidence interval for the difference in the population means of *AHE* for those with and without a bachelor's degree compu in part (7). With the confidence interval, test the following,

H_0: MeanAHE$_{bach}$ - MeanAHE $_{nobach}$ = $2.0

A. The 95% CI is $3.78- $8.01; do not reject the null

B. The 95% CI is $1.78- $8.01; do not reject the null

C. The 95% CI is $3.78- $8.01; reject the null

D. The 95% CI is $4.78- $7.01; reject the null

Compute the following four sums: $\sum_i (X_i - \bar{X})$, $\sum_i (X_i - \bar{X})^2$ $\sum_i (Y_i - \bar{Y})$ $\sum_i (Y_i - \bar{Y})^2$ where X is age and Y is average hourly of earning in 2008; The four sums are,

A. 0, 2431, 0, 27795

B. 0, 2541, 0, 3221

C. None of the above

D. -2.84, 2431, 2.9, 27795

Using Excel compute the following quantity $\sum_i (X_i - \bar{X})(Y_i - \bar{Y})$ Use this sum along with the sums in part (9) to compute sample covarian and correlation. They are

A.   20.22 and 0.45

B.   6.42 and 0.23

C.   -6.42 and -0.23

D. -20.22 and -0.45

Answers C. $12.09 and $19.12

C. 11.45 - 12.74

C. 18.02 - 20.22

D. $18.55

A. The difference, $0.57; it's NOT statistically different from 0 at the 5% level

C. - 0.91 - 2.05

A. $5.87

C. The 95% CI is $3.78- $8.01; reject the null

A. 0, 2431, 0, 27795

B.   6.42 and 0.23

ID: Empirical Exercise 3.1 (static)

31. A consumer is given the chance to buy a baseball card for $1, but he declines the trade. If the consumer is now given the baseball card, will he be willing to sell it for $1? Standard consumer theory suggests yes, but behavioral economists have found that "ownership" tends to increase the value of goods to consumers. That is, the consumer may hold out for some amount more than $1 (for example, $1.20) when selling the card, even though he was willing to pay only some amount less than $1 (for example, $0.88) when buying it. Behavioral economists call this phenomenon the "endowment effect." John List investigated the endowment effect in a randomized experiment involving sports memorabilia traders at a sports-card show.

The following table contains data from 148 randomly selected traders who attended a trading card show in Orlando, Florida in 1998. Traders were randomly given one of two sports collectables, say good A or good B, that had approximately equal market value; those receiving good A were then given the option of trading good A for good B with the experimenter; those receiving good B were given the option of trading good B for good A with the experimenter. (Good A was a ticket stub from the game that Cal Ripken Jr. set the record for consecutive games played, and Good B was a souvenir from the game that Nolan Ryan won his 300th game.)

Download the data from the table by clicking the *download table* icon   . A detailed description of the variables used in the dataset is available here [3]. Use a statistical package of your choice to answer the following questions.

Suppose that, absent any endowment effect, all the subjects prefer good A to good B. What fraction of the experiment's subjects would you expect to trade the good that they were given for the other good? (*Hint:* Because of random assignment of the two treatments, approximately 50% of the subjects received good A and 50% received good B.)

[   ]% of the subjects would trade the good that they were given for the other good.

(*Express your response as a percentage*)

Suppose that, absent any endowment effect, 50% of the subjects prefer good A to good B, and the other 50% prefer good B to good A. What fraction of the subjects would you expect to trade the good that they were given for the other good?

[   ]% of the subjects would trade the good that they were given for the other good.

(*Express your response as a percentage*)

Suppose that, absent any endowment effect, X% of the subjects prefer good A to good B, and the other (100-X)% prefer good B to good A. Show that you would expect 50% of the subjects to trade the good that they were given for the other good.

A person will trade if he received good A but prefers good B or he received good B and prefers good A. 50% receive good A, of these (100-X)% prefer good B; 50% receive good B, of these X% prefer good A. Let x = X/100. The expected fraction is:

$$[\boxed{} \times (1 - x)] + (0.5x) = \boxed{}$$

(*Round your response to two decimal places*)

Using the sports-card data   , what fraction of the subjects traded the good they were given?

The fraction of trades is [   ]

(*Round your response to two decimal places*)

Is the fraction statistically significant different from 0.50? Compute the *t*-statistic for this test.

The *t*-statistic for this test is [   ]

(*Round your response to three decimal places*)

Is the fraction statistically significant different from 0.50 at the 10% significance level?

○ **A.** Yes.
○ **B.** No.

Is there evidence of an endowment effect?

○ **A.** Yes.
○ **B.** No.

Some have argued that the endowment effect may be present, but that it is likely to disappear as traders gain more trading experience. Half of the experimental subjects were dealers, and the other half were nondealers. Dealers have more experience than nondealers.

Repeat the exercise above for dealers and nondealers.

Using the sports-card data , what fraction of *dealers* traded the good they were given?

The fraction of trades is [   ]

(Round your response to four decimal places)

Is the fraction statistically significant different from 0.50? Compute the *t*-statistic for this test.

The *t*-statistic for this test is [   ]

(Round your response to three decimal places)

Using the sports-card data , what fraction of *nondealers* traded the good they were given?

The fraction of trades is [   ]

(Round your response to four decimal places)

Is the fraction statistically significant different from 0.50? Compute the *t*-statistic for this test.

The *t*-statistic for this test is [   ]

(Round your response to three decimal places)

Is there evidence consistent with the hypothesis that the endowment effect disappears as traders gain more experience at the 1% significance level?

○ **A.** Yes.

○ **B.** No.

32. A randomized control experiment to test the utility of a health drink was conducted between two groups of individuals of the same age, height, and weight. The number of individuals in the control group and the treatment group were 105 and 100 respectively. One group (the treatment group) was asked to consume the health drink for a certain period of time and the other group (the control group) was not permitted to consume the drink for the same interval of time. The objective was to check whether the BMI (Body Mass Index) of those who consume the drink remains the same or increases significantly relative to the control group. Let $\overline{Y}_C$ denote the mean BMI of the control group and let $\overline{Y}_T$ denote the mean BMI of the treatment group. $\overline{Y}_C$ was calculated to be 20 whereas $\overline{Y}_T$ was calculated to be 30. Let the population mean for those who consume the drink be μ_T and the population mean for those who don't consume the drink be μ_C.

Which of the following hypotheses should be used to compare the causal effect of the health drink on the BMI in order to fulfill the experiment's objective?

- A. $H_0: \mu_T - \mu_C = 10$ vs. $H_1: \mu_T - \mu_C = 0$.
- B. $H_0: \mu_T - \mu_C = 0$ vs. $H_1: \mu_T - \mu_C = 10$.
- C. $H_0: \mu_T - \mu_C = 0$ vs. $H_1: \mu_T - \mu_C \neq 0$.
- D. $H_0: \mu_T - \mu_C = 0$ vs. $H_1: \mu_T - \mu_C > 0$.

Let n_C and s_C be the number of individuals and the standard deviation of the control group, and let n_T and s_T be the number of individuals and the standard deviation of the treatment group, respectively.

Complete the given table.

Group A (Control group)			Group B (Treatment group)			Difference, Treatment vs. Control				
$\overline{Y}_C$	n_C	s_C	$\overline{Y}_T$	n_T	s_T	$\left(\overline{Y}_T - \overline{Y}_C\right)$	$SE\left(\overline{Y}_T - \overline{Y}_C\right)$	95% confidence interval	t^{act}	p–value
20	105	24.56	30	100	35.86	10		([ ], [ ])		

(*Round your answers to four decimal places.*)

Considering a 5% significance level, what can be inferred from the p–value calculated above?

- A. There is no significant causal effect of the health drink on the BMI since p–value < 0.05.
- B. There is no significant causal effect of the health drink on the BMI since p–value > 0.05.
- C. There is a significant causal effect of the health drink on the BMI since p–value < 0.05.
- D. There is a significant causal effect of the health drink on the BMI since p–value > 0.05.

Answers D. $H_0: \mu_T - \mu_C = 0$ vs. $H_1: \mu_T - \mu_C > 0$.

4.3132

1.5461

18.4539

33. When testing for differences of means, you can base statistical inference on the:

  ○ **A.** normal distribution regardless of sample size.

  ○ **B.** Student t distribution if the underlying population distribution of Y is normal, the two groups have the same variances, and you use

  ○ **C.** Chi-squared distribution with $(n_m + n_w - 2)$ degrees of freedom.

  ○ **D.** Student t distribution in general.

  Answer: B.
    Student t distribution if the underlying population distribution of Y is normal, the two groups have the same variances, and you use the pooled standard error formula.

  ID: Test A Ex 3.6.3

34.
  When testing for differences of means, the t-statistic $t = \dfrac{\bar{Y}_m - \bar{Y}_w}{SE\left(\bar{Y}_m - \bar{Y}_w\right)}$, where $SE\left(\bar{Y}_m - \bar{Y}_w\right) = \sqrt{\dfrac{s_m^2}{n_m} + \dfrac{s_w^2}{n_w}}$ has:

  ○ **A.** a student t distribution if the population distribution of Y is not normal.

  ○ **B.** cannot be computed unless $n_m = n_w$.

  ○ **C.** a normal distribution even in small samples.

  ○ **D.** a student t distribution if the population distribution of Y is normal.

  Answer: D. a student t distribution if the population distribution of Y is normal.

  ID: Test B Ex 3.6.3

35. The local government of country X is committed to curb the consumption of tobacco among youngsters owing to its severe health effects. Previous attempts to regulate tobacco consumption have failed to produce any fruitful results. The only possible way out is to tax the consumption of tobacco. Optimal taxation would require a proper knowledge of how price sensitive the consumers are to tobacco consumption. Data is collected by selecting a small sample of individuals at random. It is known that the price elasticity of tobacco consumption follows a normal distribution. Similar studies carried out earlier report that the price elasticity of tobacco consumption has a mean 0.32. The current survey aims to verify whether the value of the mean population price elasticity is actually 0.32 or not.

The given table summarises the findings from the survey:

Number of individuals surveyed (n)	The standard deviation of the sample (s_Y)	The sample mean of price elasticity ($\bar{Y}$)
25	0.32	0.47

Given that the sample size is relatively small, is it reliable to assume a normal approximation to the t-statistic for hypothesis testing?

○ A. Yes, a normal approximation to the t-statistic is reliable if the population distribution is itself normal and the sample size is greater t

○ B. No, since the t-statistic follows an F distribution in small samples.

○ C. Yes, since a normal approximation to the t-statistic is independent of the sample size.

○ D. Yes, a normal approximation to the t-statistic can be used for hypothesis testing, but only with $n - 2$ degrees of freedom.

Let μ_Y denote the average price elasticity of tobacco consumption among youngsters in the entire country.

Based on the above information, the t-statistic for the test $H_0: \mu_Y = 0.32$ vs. $H_1: \mu_Y \neq 0.32$ is: [   ] .

(*Round your answer to two decimal places*).

Given the value of the t-statistic, at the 5% level of significance, we (1) ————————— the null hypothesis.

The 95% confidence interval for the mean price elasticity of tobacco consumption among youngsters in the entire country is:
([   ] , [   ]).

(*Round your answer to two decimal places*).

(1) ○ fail to reject
    ○ reject

Answers A.
   Yes, a normal approximation to the t-statistic is reliable if the population distribution is itself normal and the sample size is greater than 15.

36. Two Junior Reserve Officers' Training Corps (JROTC) cadet groups, A and B, are training for an interschool rifle shooting competition. Their coach measures their performance every day and awards them certain points according to how they may have fared on that day (A_i and B_i for groups A and B, respectively). The coach knows the average performance of both the cadet groups. The variance of the performances of both the groups is the same. He wants to forecast their pooled variance to gauge their chances at the competition. Suppose, we select 75 cadets from group A and 70 cadets from group B at random. So, the number of cadets in each group, denoted by n_a and n_b, would be 75 and 70, respectively. Let the average number of points the random sample of cadets from the groups A and B win be $\bar{A} = 15$ and $\bar{B} = 14$, respectively.

Which of the following formulas would the coach use to estimate the pooled variance, S^2_{pooled}?

○ **A.** $S^2_{pooled} = \dfrac{1}{75 + 70} \left[\displaystyle\sum_{i=1}^{75} \left(A_i - 15 \right)^2 + \sum_{i=1}^{70} \left(B_i - 14 \right)^2 \right]$.

○ **B.** $S^2_{pooled} = \dfrac{1}{75 + 70 - 2} \left[\displaystyle\sum_{i=1}^{75} \left(15 - A_i \right)^3 + \sum_{i=1}^{70} \left(14 - B_i \right)^3 \right]$.

○ **C.** $S^2_{pooled} = \dfrac{1}{75 + 70 - 2} \left[\displaystyle\sum_{i=1}^{75} \left(A_i - 15 \right)^3 + \sum_{i=1}^{70} \left(B_i - 14 \right)^3 \right]$.

○ **D.** $S^2_{pooled} = \dfrac{1}{75 + 70 - 2} \left[\displaystyle\sum_{i=1}^{75} \left(A_i - 15 \right)^2 + \sum_{i=1}^{70} \left(B_i - 14 \right)^2 \right]$.

Suppose the variances of the performances of both the cadet groups are not same.

Which of the following statements would be correct in this case? (*Check all that apply.*)

☐ **A.** The null distribution of the pooled t-statistic is not a Student t distribution, even if the data are normally distributed.

☐ **B.** The pooled variance estimator would give unbiased but inconsistent results.

☐ **C.** The pooled variance estimator would give biased and inconsistent results.

☐ **D.** The null distribution of the pooled t-statistic is a standard normal distribution for large samples.

Answers

D. $S^2_{pooled} = \dfrac{1}{75 + 70 - 2} \left[\displaystyle\sum_{i=1}^{75} \left(A_i - 15 \right)^2 + \sum_{i=1}^{70} \left(B_i - 14 \right)^2 \right]$.

A. The null distribution of the pooled t-statistic is not a Student t distribution, even if the data are normally distributed., C. The pooled variance estimator would give biased and inconsistent results.

37. The following statement about the sample correlation coefficient is true:

   ○ **A.** $-1 \le r_{XY} \le 1$.

   ○ **B.** $r_{XY}^2 \xrightarrow{p} corr(X_i, Y_i)$.

   ○ **C.** $|r_{XY}| < 1$.

   ○ **D.**
   $$r_{XY} = \frac{s_{XY}^2}{s_X^2 s_Y^2}.$$

   Answer: A. $-1 \le r_{XY} \le 1$.

   ID: Test A Ex 3.7.4

---

38. You have collected data on the average weekly amount of studying time (T) and grades (G) from the peers at your college.

   Changing the measurement from minutes into hours has the following effect on the correlation coefficient:

   ○ **A.** does not change the r_{TG}.

   ○ **B.** cannot be computed since some students study less than an hour per week.

   ○ **C.** results in a higher r_{TG}.

   ○ **D.** decreases the r_{TG} by dividing the original correlation coefficient by 60.

   Answer: A. does not change the r_{TG}.

   ID: Test A Ex 3.7.5

---

39. Assume that you have 125 observations on the height (H) and weight (W) of your peers in college. Let $S_{HW} = 68$, $S_H = 3.5$, $S_W = 68$.
   The sample correlation coefficient is:

   ○ **A.** 0.286.

   ○ **B.** 1.22.

   ○ **C.** 0.572.

   ○ **D.** Cannot be computed since males and females have not been separated out.

   Answer: A. 0.286.

   ID: Test B Ex 3.7.4

40. A low correlation coefficient implies that:

A graph with vertical axis labeled "Probability" showing two overlapping bell curves. The taller, narrower curve is labeled $\hat{\mu}_2$ and the shorter, wider curve is labeled $\hat{\mu}_1$. The horizontal axis is labeled μ at the center.

○ **A.** the line always has a flat slope.

○ **B.** the two variables are unrelated.

○ **C.** you should use a tighter scale of the vertical and horizontal axis to bring the observations closer to the line.

○ **D.** in the scatterplot, the points fall quite far away from the line.

Answer: D. in the scatterplot, the points fall quite far away from the line.

ID: Test B Ex 3.7.5

41. A researcher wants to estimate the relationship between years of educational attainment (X) and the average yearly earnings of individuals (Y). For this, he collects data from a random sample of 115 individuals. From this data, he calculates the sample variances (S_X^2, S_Y^2) and the sample covariance (S_{XY}).

If $S_X^2 = 83.15$, $S_Y^2 = 185.14$, and $S_{XY} = 116.25$, then the sample correlation coefficient will be [   ].

(*Round your answer to two decimal places*).

Which of the following statements can be inferred from the value of the sample correlation coefficient calculated above? (*Check all that apply.*)

☐ **A.** There is a strong linear association between X and Y.

☐ **B.** There is a weak linear association between X and Y.

☐ **C.** The points in the scatterplot lie very close to a straight line.

☐ **D.** The points in the scatterplot have a steep slope.

Could the researcher make general inferences about the correlation between X and Y from the sample correlation value?

○ **A.** No, because the sample correlation value changes from sample to sample.

○ **B.** No, because the sample correlation is not an efficient estimator for the population correlation.

○ **C.** Yes, because the sample correlation is a consistent estimator for the population correlation.

○ **D.** Yes, because the sample correlation is an unbiased estimator for the population correlation.

Answers 0.94

   A. There is a strong linear association between X and Y., C. The points in the scatterplot lie very close to a straight line.

   C. Yes, because the sample correlation is a consistent estimator for the population correlation.

ID: Concept Exercise 3.7.1

42. If the sample correlation between two random variables is zero, then which of the following statements could be the possible reasons behind observing this value? (*Check all that apply.*)

☐ **A.** There may exist a non-linear relationship between the two variables.

☐ **B.** There is no evident relationship between the two variables.

☐ **C.** There exists a negative linear relationship between the two variables.

☐ **D.** There exists a positive linear relationship between the two variables.

Considering a large sample, could the researcher make inferences about the population covariance from the sample covariance value?

○ **A.** Yes, because the sample covariance is an unbiased estimator for the population covariance.

○ **B.** No, because the sample covariance is not an efficient estimator for the population covariance.

○ **C.** No, because the value of sample covariance changes from sample to sample.

○ **D.** Yes, because the sample covariance is a consistent estimator for the population covariance.

Answers A. There may exist a non-linear relationship between the two variables., B.
   There is no evident relationship between the two variables.

   D. Yes, because the sample covariance is a consistent estimator for the population covariance.
